**Chlorophyll-a** is an important indicator of the health of marine ecosystems.

It reflects phytoplankton biomass and ecosystem productivity.

→ Fisheries management and biodiversity conservation

→ Harmful algal bloom detection

Source: PISCES

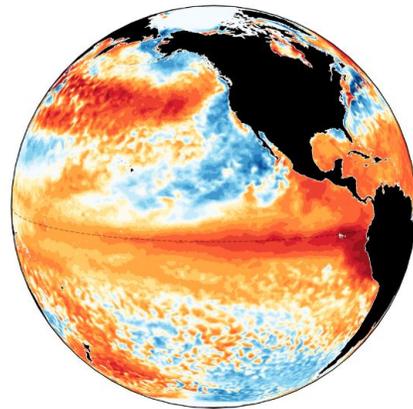

Underlying biogeochemical processes are complex and multifaceted

→ Computationally expensive and timely to model

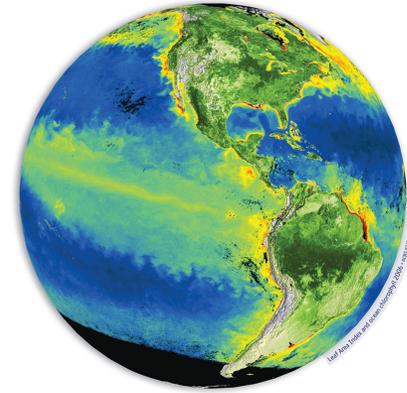

→ Difficult to parametrize

Machine learning can be used to link physical variables to biogeochemical outcomes without the need to explicitly capture these patterns.

Reanalyses, existing forecasting systems

We can use machine learning to reconstruct surface-level chlorophyll-a from physical ocean forecasts.

This has an accuracy that rivals that of the numerical model while requiring only a single GPU.
